Simply Supported Steel Beam Design Example

Simply supported steel beam design example is a fundamental topic in structural engineering that helps engineers understand the process of selecting and designing steel beams to safely support loads while optimizing material use. This article provides a detailed, step-by-step guide to designing a simply supported steel beam, incorporating critical calculations, code considerations, and best practices. Whether you're a student, a practicing engineer, or a construction professional, this comprehensive guide will enhance your understanding of steel beam design.

Introduction to Simply Supported Steel Beams

What is a Simply Supported Beam?

A simply supported beam is a structural element supported at two ends, typically with a pin support at one end and a roller support at the other. This configuration allows the beam to carry loads while providing support and stability. Simply supported beams are commonly used in bridges, floor systems, and roofs due to their simplicity and efficiency.

Importance of Proper Design

Correct design ensures that the steel beam can withstand applied loads without excessive deflection or failure. Proper design involves selecting appropriate cross-sectional shapes, calculating maximum bending moments and shear forces, and choosing suitable steel grades.

Step-by-Step Steel Beam Design Example

Problem Statement

Suppose you are tasked with designing a simply supported steel beam to carry a uniformly distributed load (UDL). The specific parameters are:

- Span length (L): 6 meters
- Uniform load (w): 20 kN/m (including dead and live loads)
- Support conditions: Pin support at the left end, roller support at the right end

- Material: Structural Steel (Grade S235 or equivalent)
- Design code: Eurocode 3 or similar (for safety and code compliance)

Your goal is to select an appropriate steel I-beam, verify the section's capacity, and ensure the design meets all safety and serviceability requirements.

Step 1: Calculating the Maximum Bending Moment and Shear Force

Bending Moment Calculation

For a simply supported beam with a uniform load, the maximum bending moment ($M_{\max}$) occurs at the mid-span and is given by:

$$M_{\max} = \frac{w \times L^2}{8}$$

Plugging in the values:

$$M_{\max} = \frac{20 \, \text{kN/m} \times (6 \, \text{m})^2}{8} = \frac{20 \times 36}{8} = 90 \, \text{kNm}$$

Shear Force Calculation

The maximum shear force ($V_{\max}$) occurs at the supports:

$$V_{\max} = \frac{w \times L}{2} = \frac{20 \times 6}{2} = 60 \, \text{kN}$$

Step 2: Selecting the Steel Section

Choosing a Candidate Section

Based on the calculated moments and shear forces, select a steel I-beam with sufficient capacity. The selection process involves consulting steel section tables (e.g., from Eurocode, AISC, or manufacturer catalogs).

Key parameters to consider:

- Section modulus (W): To resist bending
- Shear capacity: To resist shear forces

Suppose you consider a standard HEA or IPE section. For this example, an IPE 300 section is a

good starting point.

Section Properties of IPE 300

(Values approximate; consult detailed tables for exact figures)

| Property | Value |

|---|---|

| Section modulus, W_{pl} | $\sim 404 \text{ cm}^3$ |

| Area, A | $\sim 53.4 \text{ cm}^2$ |

| Depth, h | 300 mm |

| Flange width | 115 mm |

Step 3: Bending Capacity Verification

Calculating Design Bending Resistance

The design bending capacity (M_{Rd}) is calculated as:

$$M_{Rd} = \frac{W_{pl} \times \sigma_{yd}}{\gamma_{M1}}$$

Where:

- W_{pl} = section modulus
- σ_{yd} = design yield strength (for S235, approximately 235 MPa)
- γ_{M1} = partial safety factor for resistance (typically 1.0 for steel)

Assuming steel grade S235:

$$M_{Rd} = 404 \text{ cm}^3 \times 235 \text{ MPa} \times 10^{-3}$$

$$M_{Rd} \approx 94.9 \text{ kNm}$$

Since the maximum bending moment (90 kNm) is less than the section capacity ($\sim 94.9 \text{ kNm}$), the IPE 300 section is suitable for bending.

Step 4: Shear Capacity Check

Calculating Shear Resistance

The shear resistance (V_{Rd}) is:

$$V_{Rd} = \frac{A_v \times \sigma_{yd}}{\gamma_{M1}}$$

Where:

- (A_v) = shear area (approximated by the web area)
- For IPE 300, web thickness (~ 5.8 mm), web area:

$$A_v = \text{web thickness} \times \text{web height} \approx 5.8 \text{ mm} \times 300 \text{ mm} = 1740 \text{ mm}^2$$

Converting to cm^2 :

$$A_v = 17.4 \text{ cm}^2$$

Calculating shear capacity:

$$V_{Rd} = 17.4 \text{ cm}^2 \times 235 \text{ MPa} \times 10^{-1}$$

$$V_{Rd} \approx 40.9 \text{ kN}$$

Since the actual shear force is 60 kN, this section does not resist shear adequately. Additional shear reinforcement or choosing a section with a web capable of handling higher shear is necessary.

Alternative: Select a section with larger web area, such as HEA 300 or IPE 360.

Step 5: Final Section Selection and Detailing

Based on the shear capacity check, choose a section with larger web area. For example, an HEA 300:

| Property | Approximate Values |

|---|---|

| Web thickness | 6.4 mm |

| Web height | 300 mm |

| Web area | $6.4 \text{ mm} \times 300 \text{ mm} = 1920 \text{ mm}^2$ |

Calculating shear resistance:

$$V_{Rd} = 19.2 \text{ cm}^2 \times 235 \text{ MPa} \times 10^{-1} \approx 45.1 \text{ kN}$$

Still below 60 kN. Thus, a HEA 360 or IPE 400 might be necessary.

Step 6: Serviceability Checks

Beyond ultimate strength, check deflections:

- Maximum deflection ($\delta_{\max}$):

$$\delta_{\max} = \frac{5 w L^4}{384 E I}$$

Where:

- E = modulus of elasticity ($\sim 210 \text{ GPa}$)
- I = moment of inertia for the selected section

Ensure that deflections are within limits specified in the code (typically $L/250$ or $L/360$).

Additional Considerations in Steel Beam Design

Connection Design

Design appropriate supports, bolt connections, and welds to transfer loads safely.

Load Combinations

Apply relevant load combinations per code to account for various load scenarios.

Fire Protection and Durability

Consider fire protection measures and corrosion resistance for outdoor or exposed structures.

Structural Safety and Code Compliance

Always verify against local codes, standards (Eurocode, AISC, or others), and safety factors.

Conclusion

Designing a simply supported steel beam involves calculating the maximum bending moments and shear forces, selecting a section with adequate capacity, verifying the section's resistance, and ensuring serviceability limits are met. Using standard steel section tables and applying safety factors ensures that the chosen section is safe, economical, and compliant with relevant standards. This example demonstrates the process and considerations involved in steel beam design, providing a foundation for more complex structural analysis and design tasks.

Simply Supported Steel Beam Design Example: A Step-by-Step Guide

Designing a simply supported steel beam is a fundamental task in structural engineering, often serving as a cornerstone for larger, more complex projects. Whether you're an aspiring engineer or a seasoned professional revisiting core principles, understanding how to accurately analyze and design a simply supported steel beam ensures safety, efficiency, and compliance with building codes. This comprehensive guide walks you through a typical simply supported steel beam design example, illustrating each step with clarity and detail to help you master the process.

Introduction to Simply Supported Steel Beams

A simply supported steel beam is a structural element that rests on supports at its ends, free to rotate and with no moment transfer at the supports, making it a common and straightforward type of beam in construction. Its primary function is to carry loads vertically, transferring these forces to the supports. The simplicity of the support conditions makes the analytical process more straightforward compared to continuous or cantilever beams.

Fundamental Concepts and Assumptions

Before diving into the design example, it's essential to understand some foundational concepts:

- **Material properties:** The steel's yield strength (F_y), typically 250 MPa or 350 MPa, influences the

design.

- Load types: Dead loads (permanent/static) and live loads (variable/dynamic).
- Support conditions: Simply supported, allowing rotation but no horizontal movement.
- Design codes: Use relevant standards such as AISC (American Institute of Steel Construction)

specifications or Eurocode.

- Safety factors: Incorporate appropriate factors of safety as per code requirements.

Step 1: Define the Structural Parameters

Suppose we are designing a simply supported steel beam to carry a typical floor load:

- Span length (L): 6 meters (m)
- Dead load (DL): 10 kN/m (including self-weight, finishes, etc.)
- Live load (LL): 5 kN/m
- Total load (WL): $DL + LL = 15 \text{ kN/m}$

These loads are uniformly distributed, a common scenario in floor systems.

Step 2: Calculate the Maximum Bending Moment

For a simply supported beam under a uniformly distributed load:

\[

$$M_{\max} = \frac{wL^2}{8}$$

\]

Where:

- w = total load per unit length = 15 kN/m
- L = span length = 6 m

Calculating:

\[

$$M_{\max} = \frac{15 \times 6^2}{8} = \frac{15 \times 36}{8} = \frac{540}{8} = 67.5, \text{ kNm}$$

\\

This is the maximum bending moment the beam must resist.

Step 3: Select a Suitable Steel Section

Choosing the right steel section involves balancing strength, stiffness, weight, and economy. Common steel sections include I-beams (W-beams), channels, and angles. For this example, an W-beam (wide-flange) section is typical.

Assuming initial selection based on approximate sizing:

- Section choice: W250x33 (approximate weight 33 kg/m, and section modulus (S_x) around 125 cm^3)

Step 4: Check Bending Capacity

The bending capacity of a steel section is governed by its section modulus (S) and the steel's yield strength (F_y):

\\

$$M_{\text{allow}} = F_y \times S$$

\\

Assuming:

- $(F_y = 250 \text{ MPa} = 250 \text{ N/mm}^2)$
- $(S = 125 \text{ cm}^3 = 125,000 \text{ mm}^3)$

Calculate the allowable bending moment:

\\

$$M_{\text{allow}} = 250 \times 125,000 = 31,250,000 \text{ Nmm} = 31.25 \text{ kNm}$$

\\

Since the maximum bending moment from our load (67.5 kNm) exceeds this capacity, the initial section is insufficient. We need a larger section or reinforce the beam.

Step 5: Re-select or Upsize the Section

To satisfy the bending capacity, select a section with a higher section modulus. For example, a W300x55 with $(S \approx 230, \text{cm}^3)$:

$\{$

$$M_{\text{allow}} = 250 \times 230,000 = 57.5, \text{ kNm}$$

$\}$

This exceeds the required 67.5 kNm, so it's still insufficient. Next, consider a W400x82 with $(S \approx 400, \text{cm}^3)$:

$\{$

$$M_{\text{allow}} = 250 \times 400,000 = 100, \text{ kNm}$$

$\}$

Now, the capacity exceeds the applied moment, providing a safety margin.

Step 6: Check Shear Capacity

Shear forces are maximum at mid-span:

$\{$

$$V_{\text{max}} = \frac{wL}{2} = \frac{15 \times 6}{2} = 45, \text{ kN}$$

$\}$

The shear capacity of a steel section is:

$\{$

$$V_{\text{allow}} = 0.6 \times F_y \times A_{\text{web}}$$

\]

Where:

- A_{web} is the web area of the section.

Suppose the section has:

- Web thickness (t_w) = 8 mm
- Web height (h_w) = 400 mm (approximate for W400x82)

Then,

\[

$$A_{web} = h_w \times t_w = 400 \text{ mm} \times 8 \text{ mm} = 3200 \text{ mm}^2$$

\]

Calculate shear capacity:

\[

$$V_{allow} = 0.6 \times 250 \text{ N/mm}^2 \times 3200 \text{ mm}^2 = 0.6 \times 250 \times 3200 = 480,000 \text{ N} = 480 \text{ kN}$$

\]

Since 45 kN

Step 7: Check Deflection Limits

Deflection should be limited to prevent serviceability issues. The maximum deflection (δ_{max}) for a simply supported beam with uniform load:

\[

$$\delta_{max} = \frac{5wL^4}{384EI}$$

\]

Where:

- (E) = Modulus of elasticity for steel, approx. 200 GPa (200,000 MPa)
- (I) = Moment of inertia of the section

Assuming the selected section has:

$$- (I \approx 28,000, \text{cm}^4 = 28 \times 10^6, \text{mm}^4)$$

Calculate deflection:

$$\Delta_{\max} = \frac{5 \times 15,000, \text{N/m} \times (6,000, \text{mm})^4}{384 \times 200,000, \text{N/mm}^2 \times 28 \times 10^6, \text{mm}^4}$$

]

Converting all units to mm and N:

$$\Delta_{\max} = \frac{5 \times 15,000 \times 6,000^4}{384 \times 200,000 \times 28 \times 10^6}$$

]

Calculations:

- $(6,000^4 = 1.296 \times 10^{15})$
- Numerator: $(5 \times 15,000 \times 1.296 \times 10^{15} = 97.2 \times 10^{18})$
- Denominator: $(384 \times 200,000 \times 28 \times 10^6 \approx 2.15 \times 10^{15})$

Finally,

$$\Delta_{\max} \approx \frac{97.2 \times 10^{18}}{2.15 \times 10^{15}} \approx 45.2, \text{mm}$$

\]

Serviceability limits generally require deflections to be less than $(L/250)$:

\[

$$L/250 = 6000 \text{ mm} / 250 = 24 \text{ mm}$$

\]

Since the calculated deflection (~45 mm) exceeds the permissible 24 mm, the beam must be stiffened either by selecting a section with higher moment of inertia or adding stiffeners.

Summary of the Design Process

- Calculated maximum bending moment and shear force based on loadings.
- Selected a steel section with sufficient bending capacity.
- Verified shear capacity was adequate.
- Assessed deflection and identified the need for a stiffer section to meet serviceability criteria.
- Finalize the section choice based on combined strength and deflection considerations.

Additional Design Considerations

- Connection details: Bolted or welded connections should be designed considering shear, tension, and local stresses.
- Support conditions: Ensure supports can handle the reactions and are properly detailed.
- Corrosion protection: Apply appropriate coatings or specify material grades suitable for environment.
- Code compliance:

Question What are the key steps in designing a simply supported steel beam example? The key steps include determining the load conditions, calculating the maximum bending moment, selecting an appropriate beam section based on section modulus, verifying shear capacity, and checking deflection limits to ensure structural safety and serviceability. Which formulas are commonly used to calculate bending moment in a simply supported steel beam? The maximum bending moment for a uniformly distributed load is calculated using $M = wL^2/8$, where w is the load per unit length and L is the span length. For point loads, the moment is $M = PL/4$ at mid-span, where P is the point load. How do you select the appropriate steel section for a simply supported beam? Selection involves calculating the required section modulus based on the maximum bending

moment and material strength, then choosing a standard steel section (like I-beam or channel) that meets or exceeds that requirement, while also considering shear capacity and deflection limits. What are common safety and serviceability checks in steel beam design? Common checks include verifying that the bending stress is less than the yield strength divided by a safety factor, ensuring shear stress is within limits, and confirming deflections do not exceed permissible limits for serviceability. How do you account for load combinations in a simply supported steel beam design example? Load combinations follow code standards (e.g., LRFD or ASD), combining dead loads, live loads, and other applicable loads with appropriate factors to ensure the beam can safely withstand the most critical load scenarios. What role does deflection calculation play in the steel beam design example? Deflection calculations ensure that the beam's deformation remains within acceptable limits for serviceability, preventing issues like excessive sag, damage to non-structural elements, or aesthetic concerns. Are there any specific standards or codes to follow when designing a simply supported steel beam? Yes, designing steel beams typically follows standards such as AISC (American Institute of Steel Construction) Steel Construction Manual, Eurocode 3, or other relevant national codes, which provide guidelines for load assumptions, material properties, and safety factors.
